ABSTRACT

Justification Logic is a refinement of modal logic where the modality $\Box A$ is annotated with a reason $s$ for “knowing” $A$ and written $[s]A$. The expression $s$ is a proof of $A$ that may be encoded as a lambda calculus term of type $A$, according to the propositions-as-types interpretation. Our starting point is the observation that terms of type $[s]A$ are reductions between lambda calculus terms. Reductions are usually encoded as rewrite essential tools in analyzing the reduction behavior of lambda calculus and term rewriting systems, such as when studying standardization, needed strategies, Lévy permutation equivalence, etc. We explore a new propositions-as-types interpretation for Justification Logic, based on the principle that terms of type $[s]A$ are proof terms encoding reductions (with source $s$). Note that this provides a logical language to reason about rewrites.

KEYWORDS

Lambda calculus, modal logic, Curry-Howard, term rewriting, type systems

ACM Reference Format:

Justification Logic [3, 4, 19] is a modal logic where necessity is indexed by justification expressions. The modal proposition $\Box A$ becomes $[s]A$ where the justification expression $s$ is a reason for “knowing” $A$. Typically, $s$ denotes a proof that attests to the truth of $A$. An important property of Justification Logic is the reflection principle: given a proof of $A$, one can encode this proof using a justification expression $s$ and prove $[s]A$. Most formulations of Justification Logic are in Hilbert style. In that case $s$ above is a combinator, called a proof polynomial, encoding a Hilbert style proof of $A$. This paper proposes to explore the computational significance of Justification Logic via the propositions-as-types methodology. In fact, we focus here on an early precursor of Justification Logic, namely the Logic of Proofs (LP) [1, 2]. The Logic of Proofs may be understood as the justification counterpart of S4. All theorems of S4 are also theorems of LP where occurrences of the necessity modality have been suitably annotated with justification expressions. Similarly, dropping the justification expressions of modalities in theorems of Justification Logic yields S4 theorems.

Natural Deduction for the Logic of Proofs. A Natural Deduction presentation for the Logic of Proofs suggests itself through the reflection principle. Consider the following introduction rule for the modality: if $s$ is a proof of $A$, then $[s]A$ is provable, where $s$ is a justification expression denoting a Natural Deduction proof. The sequents of our deductive system take the form $\Gamma \vdash A|s$, where $\Gamma$ is a set of hypotheses and the justification expression $s$ encodes the current Natural Deduction proof of the sequent, so that we can express the above reflection principle as an introduction rule: if one proves $\Gamma \vdash A|s$, then one may prove $\Gamma \vdash [s]A|s$. The exclamation mark in "$s$" records the fact that a modality introduction rule was applied, thus updating our current justification expression. Of course, $\Gamma$ cannot be any set of hypotheses at all since otherwise $A$ and $[s]A$ would be logically equivalent (i.e. $A \Rightarrow [s]A$ and $[s]A \Rightarrow A$ would both be provable). One could restrict the hypothesis in $\Gamma$ to be modal expressions, however the resulting system would not be closed under substitution [8]. An alternative is to split them in two disjoint sets, following Bierman and de Paiva [8] and Davies and Pfenning [14]: we use $\Delta$ for modal hypotheses (those assumed true in all accessible worlds) and $\Gamma$ for truth hypotheses (those assumed true in the current world). Sequents now take the form $\Delta;\Gamma \vdash A|s$ and we can recast the above mentioned introduction rule for the modality as follows, where $\emptyset$ denotes an empty set of truth hypotheses:

\[
\frac{\Delta;\emptyset \vdash A|s}{\Delta;\Gamma \vdash [s]A|s}
\]

(1)

Although correct from a provability angle, one immediately realizes that, in the presence of this proposed rule, proofs are not closed under normalisation. This is an important requirement towards our goal in uncovering a computational interpretation of $[s]A$ since reduction on terms mimics normalisation on proofs. Indeed, normalisation of the proof of $\Delta;\emptyset \vdash A|s$ will produce a proof of $\Delta;\emptyset \vdash A|t$, for some $t$ different from $s$. We need some means of relating $t$ back to $s$.

Towards a Typed Calculus of Rewrites. A rewrite is an expression that denotes a sequence of reduction steps from a source term to a target term. Consider for example the lambda calculus term $\lambda a.a$

denoting the identity function. Let us abbreviate this term $I$. The term $(lb)(ib)$ reduces in one \(\beta\)-step to $b(lb)$ by contracting the leftmost redex. An expression denoting this reduction step would be the rewrite:
\[
ba(a,b)(lb) \triangleright (lb)(ib) \triangleright b(lb)
\]
The expression $ba(a,b)(lb)$ models the above mentioned reduction step. The symbol $ba$ is called a rule symbol since it witnesses that a rewrite rule was applied ($\triangleright$ in this case). The occurrence of $ba(a,b)$ tells us that a \(\beta\)-reduction step reduced the leftmost of the two redexes in $(lb)(ib)$. The term $(lb)(ib)$ to the left of the triangle is the source of the rewrite and $b(lb)$ on the right the target. We could continue reduction from the target $b(lb)$ to obtain $bb$. The rewrite encoding both steps would then be written:
\[
ba(a,b)(lb); ba(a,b)(lb) \triangleright (lb)(ib) \triangleright b(lb)
\]
the semi-colon denoting composition of rewrites. Rewrites are useful in studying properties of lambda calculus reduction, where the rewrite steps themselves are of interest. It is particularly useful due to the presence of syntactic accidents: two possible steps may explain $h(lb) \rightarrow_\beta lb$ both of which may be modeled with distinct rewrites.

Returning to our discussion on (1) on obtaining some means of relating $t$ back to $s$, and given that proofs are reflected as justification expressions in the logic, it seems natural to reify normalisation steps as rewrites. This suggests that:
\[
\{s\}$A$ is the type of rewrites with source $s$.

Or in terms of a deduction rule:
\[
\Delta; \emptyset \vdash \rho : s \triangleright t : A
\]
\[
\Delta; \Gamma \vdash !\rho(s,t) : [\emptyset]A
\]

A new sequent $\Delta; \emptyset \vdash \rho : s \triangleright t : A$ types rewrites rather than terms. It states that if $\rho$ is a rewrite from source term $s$ to target term $t$, then $\rho$ is a term. Since $s$ may have occurrences of rewrites and we are only interested in their source, $\rho(s,t)$ is given type $[\emptyset]A$ where $\emptyset$ projects the source of all rewrites in $s$ (for example, in the case of $\lambda x.x$ it returns $[\emptyset]$). The rest of this article is devoted to developing this propositions-as-types interpretation for the Logic of Proofs, called the Typed Rewrite Calculus (TRC), based on the ideas discussed above.

Rewrites for Higher-Order Rewriting. Although this paper is not about higher-order term rewriting (HOR), HOR is its starting point. First-order term rewrite systems are sets of rewrite rules over first-order terms. The latter are constructed from a given signature of function symbols with arity. An example is the term rewrite system consisting of two rewrite rules: $f(x) \rightarrow x, a \rightarrow b$, where $f$ has arity 1 and $a$ and $b$ have arity 0. Rewrites for first-order term rewrite systems are introduced in [31] and [30, Ch.8]. They are defined as first-order terms where the signature is extended with additional function symbols for the rules (rule symbols) and represent (equational) proofs that a term reduces to another term. For example, the reduction sequence $f(a) \rightarrow f(b) \rightarrow b$ is represented as $\varphi(a); \vartheta$ models the trivial step from $a$ to itself.\(^1\) Rewrites are equipped with simple structural properties stating, for example, that composition is associative and that, if $\rho$ is a rewrite from source $s$ to target $t$, then $\varrho; t$ is equal to $\rho$. HOR systems [30, Ch.11] are rewrite systems with binders, the paradigmatic example being the lambda calculus and its binder $\lambda$. Rewrite rules are pairs of simply typed lambda calculus with constants, following the HOAS approach [25]. For example, the $\beta$ rule as a HOR system is represented as $\lambda a.lam(x, yx), z \rightarrow yz$. Here we have function symbols $app : (\rightarrow \rightarrow \rightarrow)$ and $lam : (\rightarrow \rightarrow)$, for $\rightarrow$ some base type. Terms are assumed to be in $\beta$-normal form.\(^2\) Rewrites were extended to HOR by S. Bruggink [12, 13] following the same idea as in the first-order case, namely adding an additional rule symbol constant for each rewrite rule. Also, they are associated a source and target term. Structural equality of rewrites, as in the first order case, is also adopted so that, for example, $\varrho; t$ equates to $t$, where this time the trivial step $t$ is a simply typed term. Note that, in particular, a variable $x$ is equated to $\lambda x.x$. This has the unfortunate consequence of admitting the unsound equation [12, 13]:
\[
\vartheta =_\beta (\lambda x.x)\vartheta =_\beta (\lambda x.x); x\vartheta =_\beta \vartheta; \vartheta
\]
The rewrite $\vartheta; \vartheta$ is incorrect since the source $a$ and target $b$ of $\vartheta$ do not coincide. Lambda-calculus substitution is incompatible with rewrite composition. To avoid this obstacle, the author [12, 13] drops composition from the set of simply typed constants, thus disallowing nested rewrite composition such as in $\lambda x.x; x$. Reduction sequences are modeled as sequences of rewrites. Left pending is the problem of providing a type-system for rewrites with binders that included rewrite composition.\(^3\) We devised our Typed Rewrite Calculus with this issue in mind and believe it can remedy the problem. We embed rewrites into the typed lambda calculus by assigning them a modal type and then introduce a notion of substitution on modal variables compatible with rewrite composition. In particular, we have (we use $b$ for the trivial step from $b$ to $b$, also $u$ is a rewrite variable):
\[
!(\vartheta, a, b) = !((\vartheta;b, a, b)
\]
\[
let u \equiv \{(\vartheta, a, b) in !(u, u, u)
\]
\[
let u \equiv \{(\vartheta; a, b) in !(u, u, u, u)
\]
\[
!(\vartheta; b, b, a, b) = !(\vartheta, b, b)
\]

Although this was the initial motivation for our work, our paper focusses on the Typed Rewrite Calculus which we believe to be of interest in itself. Exploring the use of the TRC as a framework for rewrites in HOR is left to future work.

Summary of Contributions.

- A novel propositions-as-types presentation for the Logic of Proofs based on rewrites as terms.
- A notion of reduction on rewrites we dub extension.

\(^1\)This is slightly more general than our example above where, in $ba(a,s,t)$, $s$ and $t$ are terms, not rewrites. Although not required for reasoning about sequences of rewrite steps, allowing rewrites that contain rule symbols to be nested provides a concise notation reduction steps that reduce multiple, simultaneous redexes.

\(^2\)In fact, rewrites are restricted to higher-order patterns in $\beta$ normal form, where $\emptyset$ denotes the standard notion of restricted $\eta$-expansion.

\(^3\)Because we introduced proof terms (\[\ast\]-rewrites) in particular for easily defining meta-operations on reductions, we have two options: do not allow nested compositions or do not consider proof terms modulo $\beta$s-equivalence. I have opted for the second option. It is left to further research to devise an elegant form of proof term which includes nested compositions but does not have the problem observed above [13, Pg.30].
Rewrites as Terms through Justification Logic

1 TERMS AND REWRITES (AS TERMS)

This section presents (untyped) terms and rewrites. Types will be considered in Sec. 2.

Terms and Rewrites. Terms (T) and Rewrites (R) are defined by the following mutually recursive grammar:

\[ s, t ::= a | u | \lambda a. s | s t | !((p, s, t)) | \text{let } u \vdash s \text{ in } t \]
\[ \rho, \sigma ::= a | u | \beta \text{a} | \eta \text{a}s | \text{bb}(b, u, t) | \rho \sigma | \lambda a. \rho | \rho \sigma | \rho(s) | \text{let } u \vdash \rho \sigma \]

Terms include the usual lambda calculus expressions consisting of term variables, a, abstraction \( \lambda a.s \) and application \( s t \). There are also three new ones. A term of the form \( \rho(p, s, t) \) denotes a rewrite from source term \( s \) to target term \( t \). Variable \( u \) is a rewrite variable of sort term. When a rewrite \( \rho \) is substituted into a term, this variable will potentially be replaced with either the source or the target of \( \rho \), as will be made clear in the upcoming definition of substitution of rewrites. The term \( \text{let } u \vdash s \text{ in } t \) denotes rewrite composition. For example, the term \( \text{let } u \vdash b \text{ in } u \vdash a \text{ in } t \) will evaluate \( b \) to obtain a term \( \rho(p, s, t) \) and \( a \) to obtain \( \eta(s, p, q) \) and then compose the rewrites \( \rho \) and \( \sigma \) to build a rewrite \( \rho \sigma \) from the application \( s p t \) to \( t q \).

Rewrites denote reduction between a source and target term. The rewrite \( \rho(a) \) denotes the trivial reduction over term \( a \). Rewrite \( u \) is the same only that it, moreover, is subject to be replaced by rewrite substitution. Rewrite \( \text{bb}(b, a, s, t) \) models a \( \beta \)-reduction step from term \( \lambda a.s \) to term \( s(a/t) \), the latter denoting the capturing-avoiding substitution of all free occurrences of \( a \) in \( s \) by \( t \) (defined below).

The rewrite \( \text{bb}(\rho(p, s, t), u, r) \) similarly will stand for a reduction step involving a redux of the form \( \text{let } u \vdash \rho(p, s, t) \text{ in } r \), where \( u \) is to be substituted by \( \rho \), \( s \) and \( t \); further details will be supplied later. As mentioned in the introduction, the rewrite \( \rho \sigma \) denotes composition of reductions. Not all such rewrites are reasonable since the target of \( \rho \) may not coincide with the source of \( \sigma \). Making this precise requires a definition of source and target of a rewrite, a topic we address below. The remaining rewrites denote reduction under a term constructor: \( \lambda a.p \) is for reduction under an abstraction, \( \rho \sigma \) for reduction under an application, \( \text{let } u \vdash \rho \sigma \) for reduction under a let and \( \rho(s) \sigma \) for reduction under a bang term constructor, where \( s \) is assumed to be the source of \( \rho \). Reduction under a term of the form \( \eta(s, p, t) \) is interpreted as extending \( \rho \) with additional "work" as captured by the rewrite \( \rho \sigma \). In fact, \( \rho(s) \sigma \) will be considered valid only if the target of \( \rho \) coincides with the source of \( \sigma \).

Free term variables and free rewrite variables are defined as expected. Worthy of mention are the clauses: \( \text{fv}(\eta(s, p, t)) := \emptyset \) and \( \text{fv}(\text{let } u \vdash s \text{ in } t) := \text{fv}(s) \cup \text{fv}(t) \). The former owes to the fact that term variables represent truth hypothesis in the current world and hence, as is standard, cannot occur free in the term introduced by the modal type \( \eta(s, p, t) \). Similarly will stand for a reduction step from term \( \eta(s, p, t) \) to term \( t q \).

Terms and Rewrites through Justification Logic PPDP '20, September 8–10, 2020, Bologna, Italy

Rewrites as Terms through Justification Logic PPDP '20, September 8–10, 2020, Bologna, Italy
first occurrence gets replaced by ρ but the second one gets replaced by a trivial rewrite, namely τ. Accordingly, we split substitution of rewrite variables in two: one that substitutes ρ itself and another one that substitutes the source or target of a trivial rewrite. The former is written τ[u/ρ] and the latter σ[u/m] where m stands for either src or tgt. In particular, τ[u/ρ] = ρ, u[τ[src]] = s and u[τ[tgt]] = t. Note also that defining σ1; σ2[u/m] = σ1[σ2[u/m]] = σ2[u/m]; σ1[u/m] is correct but not so for τ[u/ρ]. As a final observation, both of these notions of substitution are mutually recursive. Substitution of Rewrite Variables over trivial rewrites is defined as:

\[
\begin{align*}
\sigma[u/\rho] & := \sigma, \quad u = u \\
\sigma[u/\rho'] & := \begin{cases} 
\rho, & u = v \\
\sigma, & u \neq v 
\end{cases} \\
(\lambda a. s)[u/\rho] & := \lambda a. s[u/\rho] \\
(p q)[u/\rho] & := p[u/\rho], q[u/\rho] \\
(\sigma; \rho)[u/\rho] & := \sigma[p[u/\rho], q[u/\rho]] \\
\text{(let } v := p \text{ in} q)[u/\rho] & := \text{let } v := p[u/\rho], \text{ in } q[u/\rho] \\
\end{align*}
\]

Notice the clause for (\sigma; \rho). Substitution prepends a copy of the source of σ in which ρ has been substituted (cf. rewrite v[u/\rho] above) and updates σ so that all occurrences of u in σ are replaced with the target of ρ (cf. rewrite σ[u/tgt] above). For the latter it relies on moded substitution defined below. Similar updates are applied to the source term p and trivial rewrite q. Perhaps worth mentioning is that the resulting rewrite is also a trivial rewrite: ρ ∈ ΠΣ implies ρ[u/m] ∈ ΠΣ.

Moded Substitution of Rewrite Variables over rewrites is defined as follows:

\[
\begin{align*}
\sigma[u/m] & := \begin{cases} 
\sigma, & u = u \land m = \text{src} \\
\sigma, & u = u \land m = \text{tgt} \\
\sigma, & u \neq u 
\end{cases} \\
b(a p, q)[u/m] & := b(a p)[u/m], q[u/m] \\
bb(p, v q)[u/m] & := bb(p)[u/m], v[q[u/m]] \\
(\lambda a p)[u/m] & := \lambda a. p[u/m] \\
(\sigma q)[u/m] & := \sigma[p[u/m], q[u/tgt]] \\
(\sigma; r)[u/m] & := \sigma[p[u/m], r[u/tgt]] \\
\text{(let } v := p \text{ in } r)[u/m] & := \text{let } v := p[u/m], \text{ in } r[u/m] 
\end{align*}
\]

Notice how, in the clause for u, it is the source s and target t of rewrite ρ that are substituted, prior to having being cast as trivial rewrites. Also, moded substitution still needs access to ρ itself (not just its source and target); it is used in the clause for (\sigma; r). One final comment on the above definition is that in the clause for σ; r it is safe to distribute moded substitution over σ and r.

Finally, moded Substitution of Rewrite Variables over terms is defined as:

\[
\begin{align*}
a[u/m] & := a \\
v[u/m] & := v \\
\lambda a. r[u/m] & := \lambda a. r[u/m] \\
(p q)[u/m] & := p[u/m], q[u/m] \\
(\sigma q)[u/m] & := (\sigma', p[u/m], q[u/tgt]) \\
\text{(let } v := p \text{ in } q)[u/m] & := \text{let } v := p[u/m], \text{ in } q[u/m] \\
\end{align*}
\]

For example, consider τ(τ u, s1 u, s2 u) where τ has source s1 and target s2. Then τ(τ u, s1 u, s2 u) = (s1 τ t2 s1 t1, s2 t2), for m = src or m = tgt.

Some basic, but subtle to prove, properties for substitution are presented below, after introducing structural equivalence.

Structural Equivalence and Well-Formedness. As mentioned, a rewrite may not have a source and target. If it does we say it is well-formed. For example, if a and b are distinct variables, then a; b is not well-formed. More generally, for ρ; σ to be well-formed the target of ρ must coincide with the source of σ (similar requirements apply to \l(t, s, t) and \l(p, s, t)). This leads us to consider how terms are to be compared. Since terms may include rewrites, we need to consider rewrite comparison too.

One reasonable property is that composition be associative: rewrites (\rho; \sigma); τ and ρ; (\sigma; τ) should be considered equivalent. Similarly, \rho; t should be considered equivalent to \rho, assuming that \rho and t are composable (in which case t should be equivalent to the target of \rho, though it may not be identical to it). Another example of rewrite equivalence is as follows. Let f be the term \lambda b. c. Consider the lambda calculus reduction \lambda a. (f a) → b \lambda a. c. The redex being reduced in each step is underlined. It can be represented via the rewrite \lambda a. (f b a). Such minor, structural variations are absorbed through structural equivalence.

Definition 1.1 (Source/Target Predicate; Structural Equivalence). The source/target (ST) predicate • ◦ ⊳ ∈ R × T × T is defined mutually recursively with structural equivalence • ◦ ⊳ ⊆ • ◦ ⊳ via the rules in Fig. 1. If ρ : s ⇒ t holds then we say that ρ has source s and target t. There are two structural equivalence judgements:

\[
s \equiv t \quad \text{Structurally equivalent terms} \\
\rho \equiv \sigma : s \Rightarrow t \quad \text{Structurally equivalent rewrites}
\]

If s \equiv t, then we say s and t are structurally equivalent terms. If \rho \equiv \sigma : s ⇒ t, then we say \rho and \sigma are structurally equivalent rewrites with source s and target t. In that case both \rho : s ⇒ t and \sigma : s ⇒ t hold (Lem. 1.4).

The rules defining the ST-predicate are quite expected. We comment on ST-Bang. As already mentioned, \l(\rho, s, t) is a rewrite denoting reduction under a term of the form \l(\rho, s, t) and consists of the additional "work" with which \rho is extended. The additional work is represented by the rewrite \sigma whose source must coincide with the target of \rho (modulo structural equivalence). The source and target of \l(\rho, s, t) are \l(\rho, s, t) and \l(\rho, s, t).
The rules defining structural equivalence of terms (those whose names are prefixed with \( EqT \) in Fig. 1) are as expected. The rules defining structural equivalence of rewrites (those whose names are prefixed with \( EqR \) in Fig. 1) are similar to the ones one has in first-order term rewriting (cf. Def. 8.3.1 in [38]) except for two important differences. The first is the need to rely on structural equivalence on terms to define structural equivalence on rewrites, given that terms and rewrites are mutually dependent. The other is the presence of the novel rewrite as term \(!((p; s; t), r)\). Rewrites on such terms \((p; s; t)\) and their associated equation \((p; s)\) \(\rho\) \(\vdash\) \((s; t)\) \(\rho\). The latter states how two rewrites under a bang may be composed. Given \(!((p; s; t), r)\), a rewrite \(\sigma\) extending \(\rho\) must be composable with \(\rho\) and produces \(!((p; s; t), r)\) as target. A further rewrite extending \(\rho; \sigma\), say \(\tau\), will produce term \(!((p; s; t), r; s, t)\) as target.

We next mention some lemmata on structural equivalence. The next result states that the rewrites related by structural equivalence are uniquely related.

**Lemma 1.4.** \( s \vdash p \vdash q \) implies \( p \vdash q \vdash s \).

The lemma below states that a trivial rewrite is a step over itself:

**Lemma 1.3.** \( s \vdash p \vdash q \) implies \( p \vdash q \vdash s \).

The next result states that the rewrites related by structural equivalence have the same source and target. Its proof relies on Lem. 1.3:

**Lemma 1.4.** \( p \vdash \sigma \vdash s \vdash t \) implies \( p \vdash s \vdash t \) and \( \sigma \vdash s \vdash t \).

---

**Figure 1:** Source/Target Predicate and Structural Equivalence of Rewrites and Terms
The term-as-a-trivial-rewrite operation • is compatible with structural equivalence:

**Lemma 1.5.** \( s \approx t \) implies \( \overline{s} \approx \overline{t} : s \triangleright s \).

Finally, substitution is compatible with structural equivalence too. For substitution of term variables this is proved by induction on \( s \approx t : t \).

**Lemma 1.6 (Structural Equivalence is Closed Under Substitution of Term Variables).** Suppose \( s \approx t \) and \( p \approx q \). Then \( s[a/p] \approx t[a/q] \).

For substitution of rewrite variables, the result is broken down into four items all of which are proved by simultaneous induction:

**Lemma 1.7 (Structural Equivalence is Closed Under Substitution of Rewrite Variables).** Suppose \( \tau \approx \upsilon : p \triangleright q \).

- (a) \( \rho \approx \sigma : s \triangleright t \) implies \( \rho[u/m]p \approx \sigma[v/m]q : s[u/m]p \triangleright t[u/m]p \).
- (b) \( s \approx t \) implies \( s[u/m]p \approx t[u/m]p \) if \( s ) \triangleright s \).
- (c) \( s ) \triangleright s \) implies \( s ) \triangleright s \) if \( s ) \triangleright s \).
- (d) \( s ) \triangleright s \) implies \( s[u/m]p \approx t[u/m]p \).

Having introduced the ST-predicate and structural equivalence we can now precisely state when terms and rewrites are well-formed.

**Definition 1.8 (Well-formed Terms and Rewrites).**

- (a) \( s \in \Sigma \) is well-formed if for all subexpressions of \( s \) of the form \( \{ ! ( p, q, \rho ) \} \), \( ( p, p, q ) \) is well-formed.
- (b) \( ( p, s, t ) \in \Sigma \times \Sigma \times \Sigma \) is well-formed if \( s \triangleright s \) and \( t \) are well-formed.

**Lemma 1.9 (Structural Equivalence Preserves Well-formedness).** If \( s \) is well-formed and \( s \approx t \), then \( t \) is well-formed. Similarly if \( ( p, s, t ) \) is well-formed and \( p \approx \sigma : s \triangleright t \), then \( ( p, t, s ) \) is well-formed.

We conclude the section with two important results on commutation of substitutions. We assume for these results that our objects are well-formed.

**Lemma 1.10 (Commutation of Rewrite Substitution with Term Substitution).** Suppose \( a \notin \text{fr}(p, s, t) \).

\[ p[u/m]p \approx p[a/q]u[u/m]p \]

where all three occurrences of \( m \) are either all \( \Sigma \) or all \( \Sigma \).

The second is about commutation of rewrite substitutions and requires some care. First note that when \( \bullet ( u/m )p \) commutes “over” \( \bullet ( c/m )p \) in the expression \( o[u/m]p \approx o[a/q]u[u/m]p \), a copy of \( p \) has to be prefixed in front of \( p \) leading to \( p(u/m)p \approx p(u/q)u[u/m]p \) (as witnessed in item (a) of Lem. 1.11 below). We comment on item (b) of Lem. 11, below, after having analyzed a sample proof case for item (a) which motivates the need for it.

**Lemma 1.11 (Commutation of Rewrite Substitution).** Let \( o \) be any object (i.e. term or rewrite) and suppose \( v \notin \text{fr}(p, s, t) \).

- (a) Suppose all occurrences of \( m \) below are either all \( \Sigma \) or all \( \Sigma \).

\[ o[u/m]p \approx o[a/q]u[u/m]p \]

- (b) If \( o \in \Sigma \), then

\[ o[u/m]p \approx o[a/q]u[u/m]p \]

Item (b) is motivated by analyzing the following proof case for item (a). Suppose \( o = \! ! ( \sigma, r_1, r_2 ) \) and let us introduce the following abbreviations:

\[ a^m := \bullet ( u/m )p \]

We seek to prove:

\[ \! ! ( \sigma, r_1, r_2 ) u[m/p]p u[u/m]p \]

We reason as in Fig. 2 where (**) is the property that the function that casts a term as a trivial rewrite commutes with rewrite substitution \( p(u/m)p \). The topmost box signals exactly where we apply item (b) above. Consider the case where \( r_1 = u \). If one just considers the left argument of the composition inside the box, namely \( r_2 ( u/m )p \), then the resulting term would be \( u(u/m)p \). If we now take the left argument of the composition in the second box, namely \( r_2 ( u/m )p \), then we have \( u(u/m)p ; p(u/m)p \). Clearly these rewrites are not equivalent. However, when the entire composed rewrites inside the boxes are considered, then we do obtain structurally equivalent rewrites.

2 TYPES

This section presents the type system for TRC. As mentioned in the introduction, types will include the modal type \( \Sigma \) where \( s \) is a so called source-expression.

**Types and Typing Judgements.** **Propositions** \( \Sigma \) are defined by the following grammar:

\[ A, B ::= P \mid A \sqsupset B \mid \Sigma \]

where \( P \) ranges over some set of propositional variables and \( s \) is a source-term. **Source-terms** \( s \) are terms where all references to rewrites are omitted; they are written in boldface:

\[ s, t ::= a \mid \lambda a.s \mid s.t \mid |s| \]

The s-term underlying a term can be obtained from the following translation that drops all references to rewrites:
A judgement $\Delta \vdash \sigma : A$ is well-formed if, (1) $\text{dom}(\Delta) \cap \text{frv}(\Delta, A) = \emptyset$ and (2) $\text{dom}(\Gamma) \cap \text{frv}(\Delta, \Gamma) = \emptyset$. Similarly for the rewriting judgement. These conditions state that the labels of the hypothesis are fresh.

Type System. The type system for TRC is given by the rules of Fig. 3. A judgement $\Delta; \Gamma \vdash s : A$ is derivable, indicated with $\vdash; \Delta; \Gamma \vdash s : A$, if it is provable using these rules. Moreover, we write $\vdash; \Delta; \Gamma \vdash s : A$ if it is derivable with derivation $\pi$. This notation applies to rewriting judgements too.

We next comment on the salient typing rules. The Bang rule was motivated in the introduction. Note that the type of $!(\rho, s, t)$ is $\text{Tr}$. The rule R-Bang types the rewrite that denotes reduction inside a term of the form $!(\rho, s, t)$. Reduction under such a term corresponds to extending $\rho$ with some additional work $\sigma$. The source of $(\rho, \sigma)$ is $!(\rho, s, t)$ and the target is $!(\rho, s, t)$.

Example 2.1. For any source term $p$, we can give a derivation of the proposition:

$$\vdash p A \supset \vdash p \|p\| A$$

It is presented in Fig. 4 where we omit some of the rule names to save space. Also, $A := \{u : A\}$ and $\Gamma := \{a : \|p\| A\}$.

Other theorems of TRC are:

- $\vdash s(A \supset B) \supset \vdash s A \supset \vdash s B$
- $\vdash s A \supset A$

These may be seen as annotated versions of the S4 theorems:

- $\Box (A \supset B) \supset \Box A \supset \Box B$
- $\Box A \supset A$

Remark 1. If we drop all annotations in the modality in the theorems of TRC, then we obtain theorems of (minimal) S4. This follows from observing that applying this same forgetful function on the typing rules, yields the system for S4 presented in [14]. Similarly, if we drop all references to rewrite we can prove all theorems of LP. This stems from observing that by performing this transformation on the typing rules, yields the Hypothetical Logic of Proofs [10].

Basic Metatheory of TRC. This section presents some basic metatheoretic results on TRC. First note that $\vdash; \Delta; \Gamma \vdash p : s \triangleright t : A$ implies $p : s \triangleright t$ (i.e. the triple $(\rho, s, t)$ satisfies the ST-predicate). In fact, $\vdash; \Delta; \Gamma \vdash p : s \triangleright t : A$ implies $(\rho, s, t)$ and $s$ and $t$ are well-formed (cf. Def. 1.8) and, similarly, $\vdash; \Delta; \Gamma \vdash s : A$ implies $s$ is well-formed. Typable terms can be recast as typable trivial rewrites.

**Lemma 2.2 (Term as Trivial Rewrite).** If $\vdash; \Delta; \Gamma \vdash s : A$, then also $\vdash; \Delta; \Gamma \vdash s : s \triangleright s : A$.

The proof is by induction on $\pi$. We consider here two of the interesting cases. The first one is when $\vdash; \Delta; \Gamma \vdash s : A$ is $\Delta; \vdash !((\rho, s, t)) : \text{Tr} B$ and $\pi$ ends in

$$\Delta; \vdash !((\rho, s, t)) : \text{Tr} B$$

$\Delta; \vdash !((\rho, s, t)) : \text{Tr} B$

**Bang**
Given $\vdash \Delta; \emptyset \vdash t : B$, we may apply the IH\(^8\) to obtain a derivation of $\Delta; \emptyset \vdash t : B$. Then we deduce

$$\Delta; \emptyset \vdash t : B \quad \Delta; \emptyset \vdash s : t \quad \Delta; \emptyset \vdash t : B$$

We conclude that the judgement

$$\Delta; \emptyset \vdash \langle p|s,t \rangle : \langle (p,s,t) \rangle : \llbracket \emptyset \rrbracket$$

is derivable from SEq-R. The other interesting case is when the derivation of $\Delta; \emptyset \vdash s : A$ ends in

$$\Delta; \emptyset \vdash s : A \quad \Delta; \emptyset \vdash t : A$$

In this case we resort to the IH, Lem. 1.5 and rule SEq-R.

Next we present two substitution lemmas. The first is straightforward to prove (it uses Lem. 1.6). The second (Lem. 2.4) however, is subtle and has guided the notion of substitution on rewrites that we presented in Sec. 1.

**Lemma 2.3 (Term Substitution).** Suppose $\vdash \Delta; \emptyset; a : A \vdash s : B$ and $\vdash \Delta; \emptyset \vdash t : A$. Then $\vdash \Delta; \emptyset \vdash s|a/t| : B$.

The second substitution lemma (Lem. 2.4) starts by assuming that $\vdash \Delta; \emptyset \vdash \rho : s \vdash t ; A$, $\vdash \Delta; \emptyset \vdash s : A$ and $\vdash \Delta; \emptyset \vdash t : A$. Note that typability of $s$ and $t$ from typability of $\rho$ (upcoming Lem. 2.5) is proved with the help of Lem. 2.4 itself, so we have to assume typability of all three objects at this point. We use $S$ below to denote either a term or a rewrite subject.

---

**Figure 3: Typing Rules**

\[
\begin{array}{ll}
a : A \in \Gamma & \xrightarrow{\text{Var}} \Delta; \Gamma \vdash a : A \\
\Delta; \Gamma \vdash \lambda a : B & \xrightarrow{\text{Abs}} \Delta; \Gamma \vdash \lambda s : A \supset B \\
\Delta; \Gamma \vdash \lambda a : B & \xrightarrow{\text{App}} \Delta; \Gamma \vdash t : B \\
\Delta; \emptyset \vdash \rho : s : A & \xrightarrow{\text{R-Bang}} \Delta; \Gamma \vdash \langle \rho|s,t \rangle : \llbracket \emptyset \rrbracket \\
\end{array}
\]

---

**Figure 4: Sample Type Derivation**

\[
\begin{array}{ll}
a : A \in \Gamma & \xrightarrow{\text{R-RefVar}} \Delta; \Gamma \vdash \rho : s : A \\
\Delta; \Gamma \vdash \rho : s : A & \xrightarrow{\text{R-Trans}} \Delta; \Gamma \vdash \rho : s : A \\
\Delta; \Gamma \vdash \rho : s : A & \xrightarrow{\text{R-App}} \Delta; \Gamma \vdash \rho : s : A \\
\Delta; \Gamma \vdash \rho : s : A & \xrightarrow{\text{Let}} \Delta; \Gamma \vdash \rho : s : A \\
\end{array}
\]

---

\[
\begin{array}{ll}
\Delta; \emptyset \vdash \rho : s : A & \xrightarrow{\text{Let}} \Delta; \Gamma \vdash \rho : s : A \\
\Delta; \emptyset \vdash \rho : s : A & \xrightarrow{\text{Abs}} \Delta; \Gamma \vdash \rho : s : A \\
\end{array}
\]

---

This shows why we have included the judgement $\Delta; \emptyset \vdash s : t$ in the hypothesis of Bang; it allows for structural induction on the derivation of a term.
Lemma 2.4 (Rewrite Substitution). Suppose \( \Delta; \emptyset \vdash p : s \triangleright t : A \), \( \Delta; \emptyset \vdash s : A \) and \( \Delta; \emptyset \vdash t : A \). Suppose, moreover, also that \( \vdash \Delta, u : A; \Gamma \vdash s : B \).

(a) \( S = \sigma : p \triangleright q \) implies
\( \vdash \Delta; \Gamma \vdash [u[\text{tgr}]\rho_s^q] : p[\text{tgr}] \rho_s^q \triangleright q[\text{tgr}] \rho_s^q : B[\text{tgr}] \).

(b) \( S = \sigma : p \) implies
\( \vdash \Delta, u : A; \Gamma \vdash p : B \) and \( \vdash \Delta, u : A; \Gamma \vdash q : B. \)

(c) \( S = p \) implies
\( \vdash \Delta; \Gamma \vdash p[u[\text{tgr}]\rho_s^q] : B[u[\text{tgr}]\rho_s^q] \).

(d) \( S = p \) implies
\( \vdash \Delta; \Gamma \vdash [u[\text{tgr}]\rho_s^q] : p[\text{tgr}] \rho_s^q \triangleright p[\text{tgr}] \rho_s^q : B[u[\text{tgr}]\rho_s^q] \).

(e) \( S = p \) implies
\( \vdash \Delta; \Gamma \vdash [u[\text{tgr}]\rho_s^q] : p[\text{tgr}] \rho_s^q \triangleright p[\text{tgr}] \rho_s^q : B[u[\text{tgr}]\rho_s^q] \).

The proof is by simultaneous induction on \( \vdash \Delta, u : A; \Gamma \vdash s : B \).

We will only be interested in extension on well-formed terms and well-formed rewrites. Term and rewrite extension preserves well-formedness (cf. Def. 1.8):

Lemma 3.1 (Extension Preserves Well-Formedness). \( s \triangleright t \) and \( s \triangleright \text{well-formed} \) implies \( t \triangleright \text{well-formed} \).

We next set up some auxiliary notions and results required for proving that extension of rewrites does preserve types. We begin with the definition of a step rewrite, a rewrite that corresponds to one reduction step. In other words, a rewrite that models the contraction of exactly one redex.

Definition 3.2 (Step Rewrite). Step rewrites are defined by the following grammar:

\[
\xi ::= \text{ba}(a,s,r) | \text{bb}(s,u,r) | \lambda a. \xi | \xi \triangleright \xi | \xi \triangleright s \triangleright \xi | s \triangleright \xi
\]

The next result formalizes what is intuitively clear from the definition of extension, namely that extending a rewrite consists in suffixing a step:

Lemma 3.3 (Extension Adds a Step). \( \rho : s \triangleright t \rightarrow \rho' : s \triangleright t' \) implies there exists \( \xi : s \triangleright \rho : s \triangleright t \). Moreover, \((p,s,t)\) well-formed implies \((\xi, s, t')\) well-formed.
The interesting clause in the filling operations above is when the step context is $\sigma[C]$. In particular, in the case of target filling, note how, in addition to actually inserting the target term $q$ (as may be seen from the case for $\circ$), it suffices a copy of the argument step itself: $\sigma[C(p)]$. For example, if $C = (\xi[C])$, then the source of $C[b(a,p,q)]$ will be $C[(\lambda a.p)q]$ and its target $C[b(a,p,q), (\lambda a.p)q, p(a/q)]$.

**Lemma 3.5 (Form of a Step).** Let $\xi$ be a well-formed step rewrite. Then one of the two following hold.

(a) $\xi = C[b(a,s,t)]$ and

(b) $\xi = C[b(b((\lambda a.p)q), u.r)]$ and

$$C[b(a,s,t)] : C[(\lambda a,s) t] \vdash C[b(a,s,t),(\lambda a,s) t, s[a/t]]$$

The proof is by induction on $\xi$. The only interesting case is when $\xi = \sigma[C_m]$. Since $\xi$ is well-formed we know $\sigma = m \triangleright n$ and $\xi' : n \triangleright o$ for some $m, n, o$. By the IH on $\xi'$ either case (a) or (b) holds. Assume it is (a) (the case for (b) is similar and hence omitted) then $\xi' = C[b(a,s,t)]$, for some $C'$, $a$, $s$, and $t$ and

$$\xi' : C'[(\lambda a,s) t] \vdash C'[b(a,s,t),(\lambda a,s) t, s[a/t]]$$

Since also $\xi' : n \triangleright o$, by Lem. 1.2, $n \preceq C'[(\lambda a,s) t] \vdash a \preceq C'[b(a,s,t),(\lambda a,s) t, s[a/t]]$. Then $\sigma = m \triangleright C'[(\lambda a,s) t].$ But then

$$\sigma[C'] : C[b(a,s,t)]$$

where

$$\rho : \vdash \sigma[C[b(a,s,t)]]$$

Which concludes the case.

Finally, for our Subject Extension result, it will not suffice to break down a step rewrite into its components, as described above, but also to ensure typability. Typability of the source of a step suffices to type the step itself: this may be proved by induction on the derivation of the step $\xi : s \triangleright t$.  

**Figure 5: Rewrite Extension**
Lemma 3.6 (Step Typability). \( \xi : s \triangleright t \) and \( \vdash \Delta; \Gamma \vdash s : A \) implies 
\( \vdash \Delta; \Gamma \vdash \xi : s \triangleright t : A \).

We are now in condition to prove the main result of this section, namely that extension preserves types for both terms and rewrites.

Proposition 3.7 (Subject Extension). 

(a) \( \vdash \Delta; \Gamma \vdash s : A \) and \( s \rightsquigarrow s' \) implies \( \vdash \Delta; \Gamma \vdash s' : A \).

(b) \( \vdash \Delta; \Gamma \vdash s : A \) and \( \rho : s \triangleright t \) \( \Rightarrow \) \( \rho' : s' \triangleright t' \) implies \( \vdash \Delta; \Gamma \vdash \rho' : s' \triangleright t' : A \).

We first prove (by induction on \( n \)) that 

(a) \( \vdash \Delta; \Gamma \vdash s : A \) and \( s \rightsquigarrow s' \) implies \( \vdash \Delta; \Gamma \vdash s' : A \).

(b) \( \vdash \Delta; \Gamma \vdash \rho : s \triangleright t : A \) and \( \rho \vdash s \triangleright t \) \( \Rightarrow \) \( \rho' \vdash s' \triangleright t' \) implies \( \vdash \Delta; \Gamma \vdash \rho' : s' \triangleright t' : A \).

Then we conclude from the fact that \( \vdash \Delta; \Gamma \vdash s : A \) and \( s \equiv s' \) implies \( \vdash \Delta; \Gamma \vdash s' : A \) via \( \text{Seq-T} \). Similarly, \( \vdash \Delta; \Gamma \vdash s : A \) and \( n \vdash s' \triangleright t \) implies \( \vdash \Delta; \Gamma \vdash \rho' : s' \triangleright t : A \) via \( \text{Seq-R} \). We focus on three interesting cases:

- The derivation ends in:
  \[ \Delta; \emptyset \vdash r, s : A \quad \Delta; \emptyset \vdash \rho_1 : r \triangleright s : A \]
  \[ \text{Bang} \]
  Then \( \rho_1 : r \triangleright s \rightsquigarrow r' \triangleright s' \). By the IH we have
  \[ \Delta; \emptyset \vdash r' \triangleright s' : A \quad (3) \]
  By Lem. 2.5 on (3) \( \Delta; \emptyset \vdash s' : A \). Thus we can use Bang to deduce
  \[ \Delta; \emptyset \vdash (\rho_1', r, s) : [\{r\}]A \]

- The derivation ends in:
  \[ \Delta; \emptyset \vdash r, s, r : A \quad \Delta; \emptyset \vdash \rho_1 : s \triangleright r : A \quad \Delta; \emptyset \vdash \rho_2 : r \triangleright p : A \]
  \[ \Delta; \emptyset \vdash (\rho_1, \rho_2) : ![\rho_1 ; \rho_2, s, r, p] : [\{r\}]A \]
  Then \( \rho' = (\rho_1', \rho_2') \) and \( (\rho_1, \rho_2) \) \( \Rightarrow \) \( (\rho_1', \rho_2') \) follows from \( \rho_1 : s \triangleright r \) \( \Rightarrow \) \( \rho_1' : s \triangleright r' \). By the IH \( \Delta; \emptyset \vdash \rho_2 : r \triangleright p : A \). By Lem. 2.5 \( \Delta; \emptyset \vdash \rho' : A \). Using R-Bang we deduce
  \[ \Delta; \emptyset \vdash \rho_1, \rho_2' : ![\rho_1 ; \rho_2', s, r, p] : [\{r\}]A \]

- The derivation ends in:
  \[ \Delta; \emptyset \vdash b(a, p) : \langle \lambda a.p \rangle q \triangleright p(a, q) : A \]
  \[ \Delta; \emptyset \vdash b(a, p) : \langle \lambda a.p \rangle q \triangleright p(a, q) : A \]
  \[ \text{R-\beta} \]

Suppose \( ba(a, p, q) : \langle \lambda a.p \rangle q \triangleright p(a, q) \) \( \Rightarrow \rho' : \langle \lambda a.p \rangle q \triangleright t' \). By Lem. 3.3 ( \( \Rightarrow \subseteq \Rightarrow \) ), \( \rho' \) \( \Rightarrow \rho(a) q \triangleright t' \) for some step \( \xi \). By Lem. 1.4, \( ba(a, p, q) : \langle \lambda a.p \rangle q \triangleright t' \). By a simple generation lemma, there exists \( t'' \) such that \( ba(a, p, q) : \langle \lambda a.p \rangle q \triangleright t'' \) and \( \xi : t'' \triangleright t' \). By Lem. 3.5 on \( \xi \), one of the two following hold.

(a) \( \xi = C(b(a, m, n)) \) and 
\[ C(b(a, m, n)) : C[\langle \lambda b.m \rangle n]^{\text{src}} \rightarrow C[\langle \lambda b.m \rangle n, m, b/n \}]^{\text{tgt}} \]

(b) or \( \xi = C(b(b(a, m, n))) \) and 
\[ C(b(b(a, m, n))) : C[\langle \lambda b.a.m \rangle n]^{\text{src}} \rightarrow C[\langle \lambda b.a.m \rangle n, m, b/n \}]^{\text{tgt}} \]

We assume that case (a) holds, case (b) is dealt with similarly and omitted. By Lem. 1.2, \( t'' \approx C[\langle \lambda b.m \rangle n]^{\text{src}} \) and \( t'' \approx C[\langle \lambda b.m \rangle n, m \triangleright b/n]^{\text{tgt}} \). By Lem. 1.2, on \( ba(a, p, q) : \langle \lambda a.p \rangle q \triangleright t'' \) and the hypothesis, \( t'' \approx p(a, q) \). By Lem. 2.5 \( p(a, q) \) is typable. That is, \( \vdash \Delta; \emptyset \vdash p(a, q) : A \). Then the term 
\[ C[\langle \lambda b.m \rangle n]^{\text{src}} \] is typable too by \( \text{Seq-T} \). By Lem. 3.6, we obtain 
\[ \Delta; \emptyset \vdash C(b(a, m, n)) : p(a, q) : A \]
where
\[ o_1 := C[\langle \lambda b.m \rangle n]^{\text{src}} \]
\[ o_2 := C[\langle \lambda b.a.m \rangle n, m, b/n \}]^{\text{tgt}} \]

We conclude from Trans and \( \text{Seq-R} \).

Confluence and Strong Normalization. Rewrite extension is certainly not confluent. For example, the rewrite \( \text{I}(l_a) : \text{I}(l_a) \triangleright \text{I}(l_a) \) from above, in addition to be extended as depicted in (2), can also be extended as follows:

\[ \text{I}(l_a) : \text{I}(l_a) \triangleright \text{I}(l_a) \rightarrow \text{ba}(b, 1a) : \text{I}(l_a) \triangleright 1a \rightarrow \text{ba}(b, 1a) \rightarrow \text{ba}(b, 1a) \rightarrow \text{a} \]

Clearly \( \text{I(ba(b, a)))} \neq \text{ba}(b, 1a) \neq \text{ba}(b, b, a) \). This is expected since structural equivalence does not include permutation of redexes as in \( \text{L}^{-} \) permutation equivalence [20]. However, rewrite extension is strongly normalizing. This is proved by a simple mapping, called the target mapping, of rewrite extension steps to \( \beta \)-steps in the simply typed lambda calculus (\( \lambda^{-} \)).

\[ U(a) := a \]
\[ U(u) := u \]
\[ U(\lambda a.U(s)) := \lambda a.U(s) \]
\[ U(t) = U(s) \]
\[ U((\rho, s), t) := U(t) \]
\[ U((\rho, s), t) := U(t) \]

First two simple results, both proved by induction, relate the target mapping, substitution and structural equivalence.

Lemma 3.8. 

(a) \( U(r(a/s)) = U(r)[a := U(s)] \) for any term \( r \).

(b) \( U(r(u/w) \rho'_2) = U(r)[u := U(t)] \)

(c) \( U(\lambda a.U(t)) \) for any type \( A \).

Lemma 3.9. (a) \( \text{If } r = r' \text{ then } U(r) = U(r') \).

(b) \( \rho : s \triangleright r \text{ then } U(\rho) : s \triangleright U(\rho) \).

Rewrite extension steps map to \( \beta \)-reduction steps. The proof is by induction using Lem. 3.9 and Lem. 3.8.

Lemma 3.10. (a) \( \rho : s \triangleright r \) implies \( U(r) = \beta U(s) \)

(b) \( \rho : s \triangleright r \text{ then } U(\rho) : s \triangleright U(\rho) \rightarrow \beta U(\rho) \)

Finally, we address preservation of typability. If \( \Lambda = \{ u_1 : A_1, \ldots, u_n : A_n \} \) is a set of rewrite hypotheses and \( \Gamma = \{ a_1 : B_1, \ldots, a_m : B_m \} \) is a set of term hypotheses, let us write \( U(\Delta; \Gamma) \) for the typing context \( \{ u_1 : U(A_1), \ldots, u_n : U(A_n), a_1 : U(B_1), \ldots, a_n : U(B_n) \} \) in \( \lambda^{-} \).

Lemma 3.11. 

(a) \( \vdash \Delta; \Gamma \vdash s : A \) implies \( \vdash U(\Delta; \Gamma) \vdash U(s) : U(A) \)

(b) \( \vdash \Delta; \Gamma \vdash s \triangleright t : A \) implies \( \vdash U(\Delta; \Gamma) \vdash U(s) \rightarrow U(t) : U(A) \) in \( \lambda^{-} \).
Proof. The proof is by simultaneous induction on the derivation \( \pi \). Most cases are straightforward by resorting to the IH when appropriate. Some of the interesting cases are:

- **B-bang**: Let \( \Delta; \Gamma \vdash !\langle p, r, s \rangle \colon \mathcal{F}A \) be derived from \( \Delta; \emptyset \vdash r, s : A \) and \( \Delta; \emptyset \vdash p : r \triangleright s : A \). By IH on the last premise we have that \( U(\Delta; \emptyset) \vdash U(p : r \triangleright s) : U(A) \). Moreover, \( U(p : r \triangleright s) = U(s) \) and \( U(\mathcal{F}A) = U(A) \), so we may conclude by weakening.

- **L-Lem**: Let \( \Delta; \Gamma \vdash \langle u \equiv s \triangleright t \rangle \colon C[u/p] \) be derived from \( \Delta; \Gamma \vdash t : C[u/p] \) and \( \Delta, u : A; \Gamma \vdash t : C \). By IH we have that \( U(\Delta; \Gamma) \vdash U(s) : U(A) \) and that \( U(\Delta; \Gamma), u \vdash U(A) \vdash U(t) : U(C) \). So \( U(\Delta; \Gamma) \vdash U(\langle u \equiv s \triangleright t \rangle) = (\lambda u.U(t)/U(s)) : U(C) \). We conclude by Lemma 3.8, given that \( U(C) = U(C[u/p]) \).

- **R-Bang**: Let \( \Delta; \Gamma \vdash \langle p!; \sigma \rangle \colon !\langle p, r, s, t \rangle \colon \mathcal{F}A \) be derived from \( \Delta; \emptyset \vdash s, r, t : A \) and \( \Delta; \emptyset \vdash p : s \triangleright r \vdash t : A \). By IH we have that \( U(\Delta; \emptyset) \vdash U(t) : U(A) \). Moreover, \( U(\langle p!; \sigma \rangle) = \langle p!, s, r, t \rangle \vdash \langle p, r, s, t \rangle = (\lambda u.U(t)/U(s)) = U(t) \) and \( U(\mathcal{F}A) = U(A) \), so we may conclude by weakening.

- **R-β**: Let \( \Delta; \Gamma \vdash \langle \langle a.s, t \rangle \triangleright s/t \rangle \colon B \) be derived from \( \Delta; \emptyset \vdash a : s : B \) and \( \Delta; \Gamma \vdash t : C \). By IH, \( U(\Delta; \Gamma), a : U(A) \vdash U(s) : U(s) \) and \( U(\Delta; \Gamma) \vdash U(t) : U(A) \). So by the (standard) substitution lemma we have that \( U(\Delta; \Gamma) \vdash U(t) : U(A) \) holds by definition. By the (standard) substitution lemma we have that \( U(\Delta; \emptyset) \vdash U(r) : U(A) \) holds by the IH, and \( U(\Delta; \emptyset) \vdash U(r) : U(A) \). Moreover, \( U(\langle \langle a.s, t \rangle \triangleright s/t \rangle \colon B) \vdash \langle u \equiv s \triangleright t \rangle \colon C[u/p] \) and \( \langle u \equiv s \triangleright t \rangle \colon C[u/p] \) by Lemma 3.8, so by weakening we conclude this case.

The following is an immediate consequence of Lem. 3.11, Lem. 3.10, and strong normalization of the simply typed lambda calculus [6].

**Corollary 3.12.** Rewrite extension is strongly normalizing.

## 4 RELATED WORK

Propositions-as-types for modal logic has an extensive body of literature which would be impossible to summarize here. We refer the reader to [15, 18] for further references. We focus instead on Justification Logic and the Logic of Proofs. Artemov introduced LP in [1, 2]. It was presented as the missing link between the provability interpretation of classical S4 and provability in PA (Peano Arithmetic). The more general setting of Justification Logic was presented in [4]. A recent survey is [16] and recent texts [3, 19]. For Natural Deduction and Sequent Calculus presentations consult [2, 5, 11]. Computational interpretation of proofs in JL is studied in [5, 7, 9, 26–28]. The first-order logic of proofs is studied in [29].

Regarding rewrites, as mentioned, they are studied in [30, 31] for first-order rewriting and are dubbed *proof terms*. See Rem. 8.3.25 in [30] for additional references. They are related to Meseguer’s Rewriting Logic [23]. Proof terms are used as a tool to prove various properties of first-order term rewriting systems (such as that various notions of equivalence of reductions coincide). A theory of proof terms for the typed lambda calculus was developed by Hilken [17]; however proof terms themselves are not reified as terms. An extension to arbitrary higher-order term rewriting systems was given by Brüggenk in [12] with the drawbacks discussed in the introduction. A notion of proof term was also developed for infinitary (first-order) rewriting [21] and used for studying equivalence of infinitary reductions [22].

Dependent types (DT) [24] includes types that depend on terms and corresponds to the propositions-as-types interpretation of first-order logic. DT lacks the primitive finite reflection principle from LP. However, the Logic of Proofs is similar to DT in that the modality also depends on terms. This leads one to ponder on the suitability of resorting to a rule such as DT’s conversion rule to circumvent the issue from the introduction, namely that normalisation of the proof \( \Delta; \theta \vdash A \) in (1) will produce a proof of \( \Delta; \theta \vdash A \) for some \( t \) different from \( s \). The conversion rule from DT states that from \( \Gamma \vdash A \) and \( A \equiv B \), one infers \( \Gamma \vdash B \), where \( A \equiv B \) is some notion of equivalence of types that typically includes conversion for terms. This seems problematic in at least two aspects. Our sequents have the form \( \Gamma; \Delta \vdash A \), where \( s \) keeps track of the current derivation under construction. Conversion would replace \( A \) with an equivalent type \( B \), resulting in \( \Gamma; \Delta \vdash B \). However, \( s \)’s role is to encode the current derivation being constructed, would have to be updated to reflect the application of conversion, to say \( eq(s, e) \) where \( e \) is an encoding of the derivation of \( A \equiv B \):

\[
\Gamma; \Delta \vdash A | s \quad A \equiv B | e \\
(\Gamma; \Delta \vdash B | eq(s, e)) \quad \text{Conv}
\]

Since \( s \) is not present and \( eq(s, e) \) are distinct, the issue with closure under normalisation remains. Another potential issue with a conversion like rule to address the issue with (1) discussed in the introduction is that in hypotheses of the form \( \langle u \rangle A \) there is no assumption that \( s \) is a proof of \( A \) (in fact, it may not be typable at all). The reason for this is that the Logic of Proofs is capable of realizing all IS4 theorems. Take, for instance, the IS4 theorem \( \Theta (\cdots \perp \cdots) \) where \( A \equiv \perp \). In our TRC, there are \( s \) and \( t \) such that \( \langle s \rangle (\langle \langle \perp \rangle \rangle \langle \perp \rangle) \) is derivable.\(^9\) Note, however, that there is no proof of \( \perp \) given that the system is consistent. A conversion like rule cannot assume even typability of \( s \) in \( \langle s \rangle A \).

### 5 CONCLUSION

We present a novel propositions-as-types interpretation of the Logic of Proofs, dubbed the *Typed Rewrite Calculus* or TRC, in which reductions between terms are reified as terms. Consider simply typed terms \( s \) and \( t \) and a reduction from \( s \) to \( t \). Such reductions may be expressed as terms too, called rewrites or proof terms. An example rewrite \( p \) is \( ba(a, b) b a(b, a, b) \) (cf. the introduction), denoting the reduction sequence from \( (ba)(ba) \) to \( ba \). What is the type of a rewrite? If \( A \) is the type of the source \( (ba)(ba) \), then we propose the modal type \( \langle (ba)(ba) \rangle A \) as the type of \( p \). More generally, \( \langle s \rangle A \) is

\( ^9 \text{Take } s \text{ to be } \lambda a^{pU} . \text{let } u \equiv a \text{ in } u \text{, for any } t \text{, where we have decorated the type of } a \text{ for clarity.} \)
